Black space and white space per core product

How the Power BI report shows, per sales unit and core product, where we already sell and where we can still grow, and what that is worth.

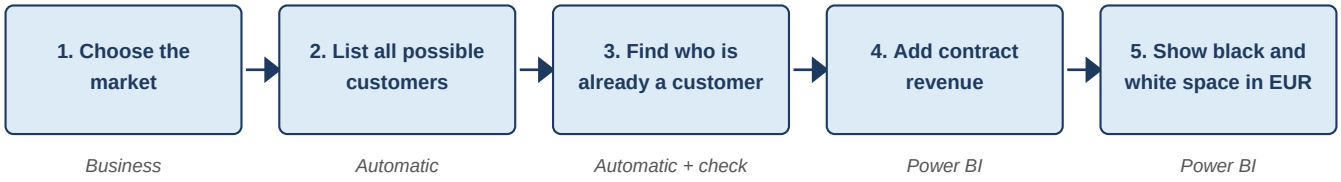
The question the report answers

For every core product: **which government organisations could buy it** (the market), **which of them already pay for it**, and **how much revenue is still out there**. You see this per sales unit, per core product and per country (Netherlands, Belgium, Germany, the Dutch Caribbean and Suriname).

Five words to know

TAM	Total addressable market: all organisations that could realistically buy this core product.
Black space	Organisations in the TAM that already have a recurring contract for this core product.
White space	Organisations in the TAM that do not (yet). This is the growth potential.
Inhabitants	Every organisation carries the number of inhabitants it serves. A cooperation of five municipalities serves the inhabitants of all five.
ARPU	Average revenue per inhabitant we earn today with this core product, used to put a euro value on the white space.

The flow in five steps



1. Choose the market. Per sales unit, core product and country, the business fills in one row in an Excel template: which kinds of organisations belong to the market (for example municipalities and inter-municipal cooperations), which kinds to leave out (for example waste or recreation bodies), and a minimum size (for example at least 10,000 inhabitants, because smaller ones rarely buy).

2. List all possible customers. A program builds one complete list of government organisations from official public registers (national statistics offices and government organisation registers), not from memory or guesswork. Every organisation gets its type and the inhabitants it serves. It then applies the choices from step 1.

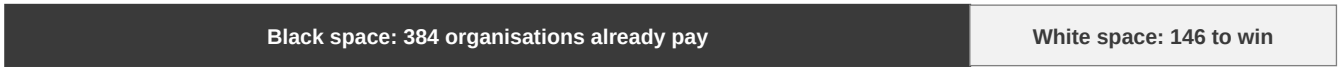
3. Find who is already a customer. Each organisation is linked to our own CRM accounts: first by fixed rules (Chamber of Commerce number, exact name), then by AI for the harder cases (old names of merged municipalities, departments, spelling). Every link shows how sure it is; the team checks the uncertain ones and can correct any link in the template.

4. Add contract revenue. Power BI combines this list with our recurring contract revenue (subscriptions only, no one-off sales) per account and core product.

5. Show black and white space. Organisations with recurring revenue for the core product are black space, the rest is white space. Power BI then puts a euro value on the white space (see page 2).

What you will see in the report

Example: total addressable market (TAM) for core product X in one country = 530 organisations



Per sales unit and core product (and filterable per country and type of organisation) the report shows a table like the example below. *All numbers on this page are made up for illustration.*

Sales unit	Core product	TAM (orgs)	Black space (customers)	White space (to win)	White space value / year	Winnable per year
Sales unit A	Core product X	530	384	146	EUR 210,000	EUR 21,000
Sales unit A	Core product Y	342	120	222	EUR 480,000	EUR 48,000
Sales unit B	Core product Z	1,250	310	940	EUR 1,150,000	EUR 115,000

You can open each line to see the actual organisations: which ones pay, which ones do not, and how many inhabitants each serves.

How the euro value is calculated

White space value	For each organisation in the white space: **inhabitants x ARPU per inhabitant x factor**. The ARPU comes from what municipalities pay us today. The factor corrects for the type of organisation: a province pays far less per inhabitant than a municipality (for example 10%). The business sets these factors per core product and country in the same template.
Winnable per year	Customers do not switch every year. We use our own average churn: with 10% churn a customer stays about 10 years, and we assume the same for competitors. So about **10% of the white space comes up for grabs each year**. This is a simple estimate: as our market share grows, the winnable part shrinks.
Cooperations	When a cooperation (for example a shared service centre of five municipalities) holds the contract, its member municipalities can count as covered, so they do not show up as white space by mistake.

Good to know

• The list of organisations comes from official registers and is refreshed once a year, together with a fresh export of our CRM.

• Some organisations have no known number of inhabitants (for example cooperations of provinces or water boards). They are marked, so the report can show them separately instead of silently leaving them out.

• If the report shows a paying customer as white space, the link to our CRM is usually missing. The team fixes this in the template and the next run picks it up.

• Organisations below the minimum size or of an excluded type stay visible with the reason, so nothing disappears without explanation.

Who does what

Business	Chooses the market per core product and country (step 1), sets the factors and checks uncertain links.
Data team	Runs the yearly refresh (registers, CRM export, linking) and delivers one Excel file for Power BI.
Power BI	Combines the file with recurring revenue and shows black space, white space and their value.
